

CLEO Results on Charmonium and Charm

Helmut Vogel
Carnegie Mellon University

(for the CLEO Collaboration)
QCD08 Montpellier, France

Charmonium: First observation of $J/\psi \rightarrow 3\gamma$
Exclusive decays of χ_{cJ}
Properties of η_c and h_c

Light systems: $\psi(2S) \rightarrow \eta J/\psi$: η BF's and $M(\eta)$
 $\psi(2S) \rightarrow \pi^+\pi^- J/\psi$, $J/\psi \rightarrow \gamma \eta'$: $M(\eta')$

Open Charm: f_D and f_{D_s} (a puzzle?)
Discovery of $D_s \rightarrow p \bar{n}$

Detector and Data Samples

CLEO-III: Silicon Vertex Detector;
 B=1.5T
 CLEO-c: Inner Drift Chamber;
 B=1.0T

Detector	Energy GeV or QQ resonance (targeted $Q\bar{q}$ meson)	Luminosity fb^{-1}	Narrow resonance statistics
CLEO-III	11.227-11.383	0.71	
	Y(5S) (B_c)	0.42	
	Y(4S) (B) + cont	6.2 + 2.2	
	Y(3S) + cont	1.2 + 0.2	6M
	Y(2S) + cont	1.2 + 0.4	9M
	Y(1S) + cont	1.1 + 0.2	22M
	6.9 – 8.4	0.02	
CLEO-c	4.17 (D_c)	0.586	
	3.97-4.26	0.06	
	$\psi(3770)$ (D)	0.818	
	$\psi(2S)$	0.054	27M
	3.673	0.021	

$B(\psi(2S) \rightarrow \pi^+\pi^- J/\psi) = 32\%$ ($\epsilon \approx 75\%$)

$B(\psi(2S) \rightarrow \gamma \chi_{cJ}) \approx 9\%$ for each $J=0,1,2$

Clean, tagged, abundant $J/\psi, \chi_{cJ}$ data!

J/ψ → 3γ

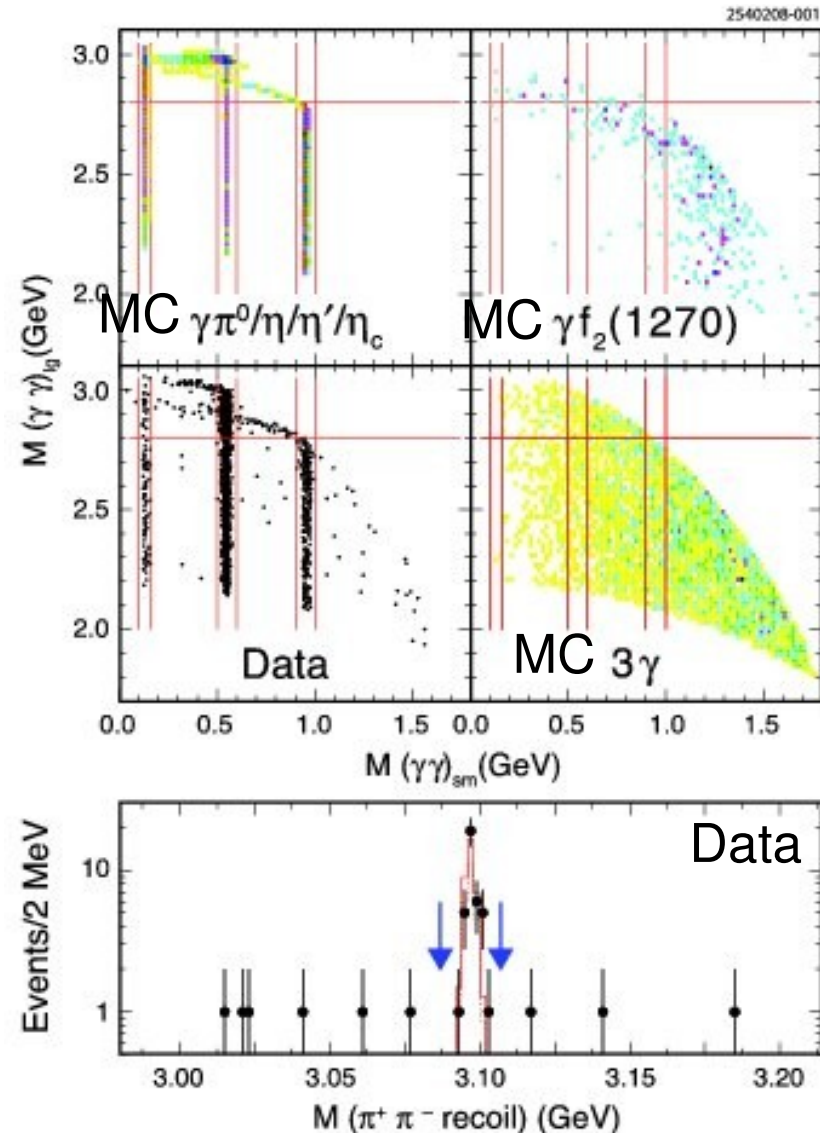

Tag via $\psi(2S) \rightarrow \pi^+\pi^- J/\psi$
(eliminates QED background!)

Veto resonances $\pi^0, \eta, \eta', \eta_c$

Main remaining background:

$J/\psi \rightarrow \gamma \pi^0 \pi^0$

Tagging gives very clean J/ψ
sample!

$J/\psi \rightarrow 3\gamma$

Perform kinematic fit;

Signal peaks at low χ^2/dof

Background rises away from zero

(and is independent of $\pi^0\pi^0$ substructure!)

Result (arXiv:0806.0671 [hep-ex]):

$B = (1.2 \pm 0.3 \pm 0.2) \times 10^{-5}$ (6σ)

First observed 3γ decay of any hadron!

Theory: QED: $B(3\gamma)/B(3g) \approx (\alpha/\alpha_s)^3$

and $B(3\gamma) \approx (\alpha/14)B_{\mu\mu} \approx 3 \times 10^{-5}$

But QCD corrections difficult & uncertain!

Exclusive Decays of χ_{cJ}

$\psi(2S)$ is a χ_{cJ} factory:

$B(\psi(2S) \rightarrow \gamma \chi_{cJ}) \approx 8-10\%$
for each of $J=0,1,2$ ($>2M$ each)

Can probe exclusive decays
down to $BR \approx 10^{-4}$

**Gluonic environment in χ_{cJ} decay
differs from J/ψ , $\psi(2S)$ decay**

Studied 14 exclusive decay modes
(13 hadronic + $\gamma\gamma$)

$\chi_{cJ} \rightarrow 2$ hadrons: color octet contribution?

$\chi_{cJ} \rightarrow \gamma\gamma$

“pure” QED? Relativistic & rad' corrections!
wide range of predictions and measurements
for rate

$\chi_{cJ} \rightarrow \eta(') \eta(')$

single-OZI vs double-OZI

$\chi_{cJ} \rightarrow$ baryon antibaryon

puzzling relative production rates

$\chi_{cJ} \rightarrow$ multi-hadrons

resonant substructure, isospin relations, etc.

$$\chi_{cJ} \rightarrow M\bar{M}, M=\pi, K$$

($\chi_{c1} \rightarrow PP$ is forbidden)

Previous measurements had uncertainties of 10% or larger

Clean signals seen in CLEO data

CLEO uncertainties $\leq 10\%$

Ratios:

	χ_{c0}	χ_{c2}
$K_S K_S / K^+ K^-$	0.54 ± 0.03 Belle: 0.49 ± 0.11	0.47 ± 0.05 Belle: 0.70 ± 0.24
$\pi^0 \pi^0 / \pi^+ \pi^-$	0.46 ± 0.05	0.43 ± 0.13
$K_S K_S / \pi^+ \pi^-$	0.55 ± 0.03 Belle: 0.46 ± 0.11	0.33 ± 0.03 Belle: 0.40 ± 0.12

Belle PLB 651, 15 (2007)

CLEO improves upon precision, is consistent with Belle and with isospin counting expectations,

$$K_S K_S : K^+ K^- = 1:2$$

$$\pi^0 \pi^0 : \pi^+ \pi^- = 1:2$$

egie Mellon

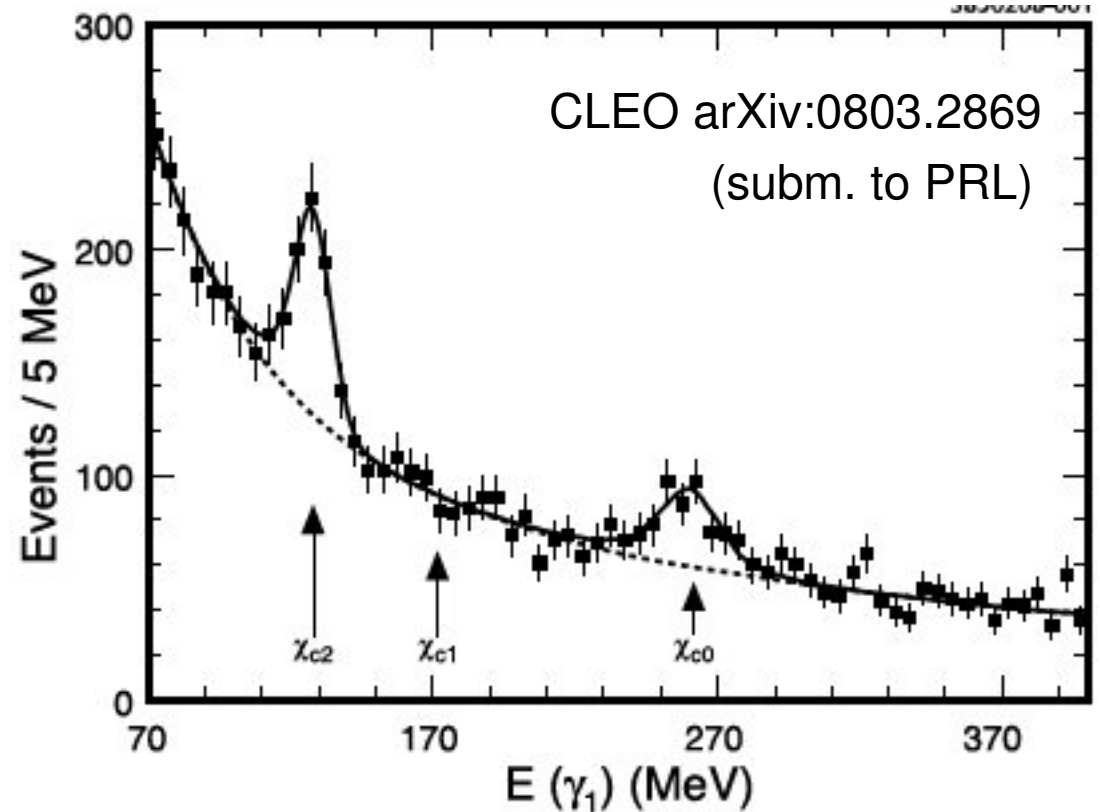

$$\chi_{cJ} \rightarrow \gamma\gamma$$

$\chi_{cJ} \rightarrow \gamma\gamma$ is pure QED in first approximation

Decay rates \Rightarrow relativistic and radiative corrections (significant in the charmonium system!)

$\Gamma(\chi \rightarrow \gamma\gamma)$ measurements range from 2-4keV, with smallest error 0.6keV

Result: $\Gamma_{\gamma\gamma}(J=2) = (0.60 \pm 0.06 \pm 0.03 \pm 0.05) \text{ keV}$

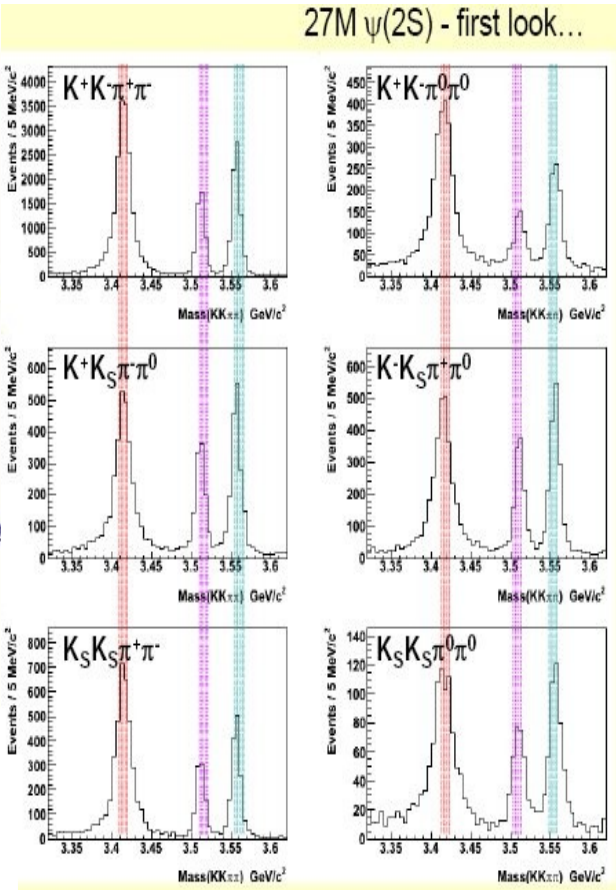

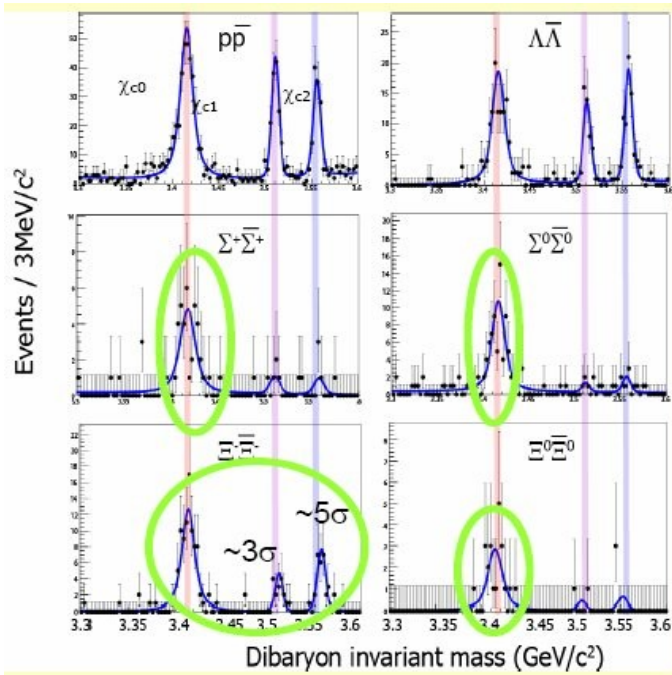

$\Gamma_{\gamma\gamma}(J=0) = (2.53 \pm 0.37 \pm 0.11 \pm 0.24) \text{ keV}$

Important quantity is $R = \Gamma_{\gamma\gamma}(J=2)/\Gamma_{\gamma\gamma}(J=0)$

(cancellations in pQCD), $R_{th} = (4/15)(1 - 1.76\alpha_s)$

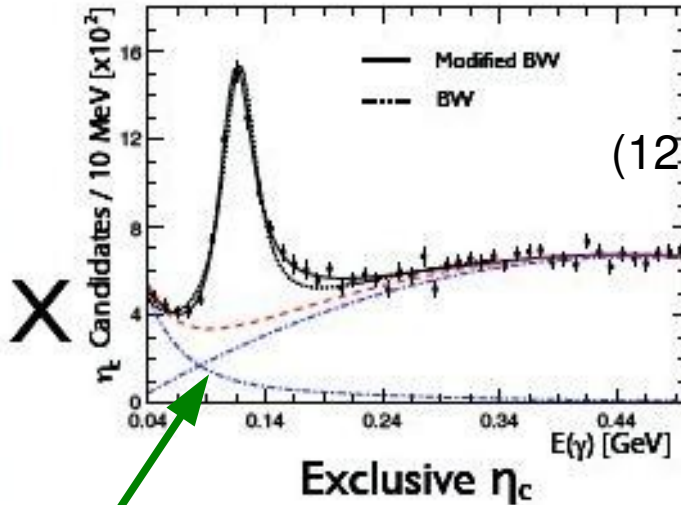

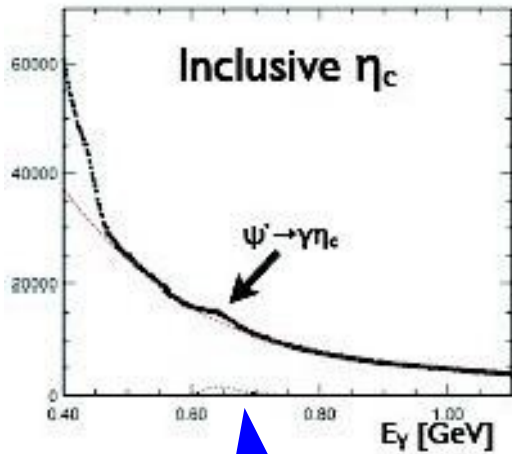

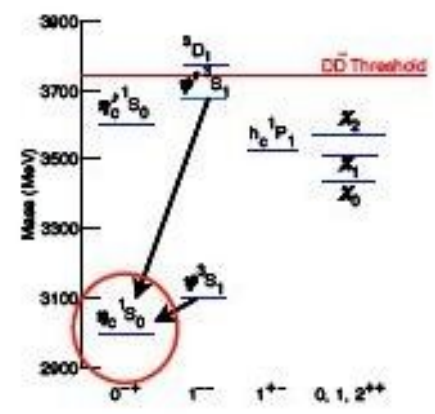

$R_{th}(\alpha_s=0.32) = 0.12$, vs. $R_{exp}(\text{world avg}) = 0.20 \pm 0.02$

Picture book of more exclusive χ_{cJ} decays

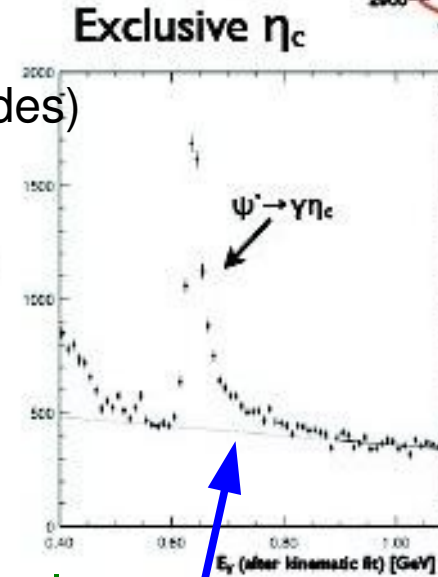

All CLEO. Many are First Observations, or more precise than previous world averages!

$J/\psi, \psi' \rightarrow \gamma \eta_c$

(12 modes)

$=B(J/\psi \rightarrow \gamma \eta_c)$

$J/\psi \rightarrow \gamma \eta_c$: **DIRECT M1** transition

Inclusive rate measurement difficult:
low γ energy, unknown bkgd shape.
Use exclusive event reconstruction.

$\psi(2S) \rightarrow \gamma \eta_c$: **HINDERED M1** transition

Must take into account the high-energy tail in the signal shape.

We do both inclusive analysis (counting!) and exclusive event reconstruction.

$J/\psi, \psi' \rightarrow \gamma \eta_c$

Results: CLEO arXiv: 0805.0252
(submitted to PRL)

$$B(\psi(2S) \rightarrow \gamma \eta_c) = (4.32 \pm 0.16 \pm 0.60) \times 10^{-3}$$

PDG06: $(2.6 \pm 0.4) \times 10^{-3}$

Theory: difficult: M.E. suppressed in HINDERED M1

$$(J/\psi \rightarrow \gamma \eta_c) / (\psi(2S) \rightarrow \gamma \eta_c) = 4.59 \pm 0.23 \pm 0.64$$

$$B(J/\psi \rightarrow \gamma \eta_c) = (1.98 \pm 0.09 \pm 0.30)\%$$

PDG06: $(1.3 \pm 0.4)\% \rightarrow \Gamma_{\gamma \eta_c} = (1.2 \pm 0.3) \text{ keV}$

Theory (LQCD, Dudek et al., 2007): $\Gamma_{\gamma \eta_c} = (2.0 \pm 0.1 \pm 0.4) \text{ keV}$

(Now good agreement -- discrepancy resolved!)

As “byproduct”, can calculate

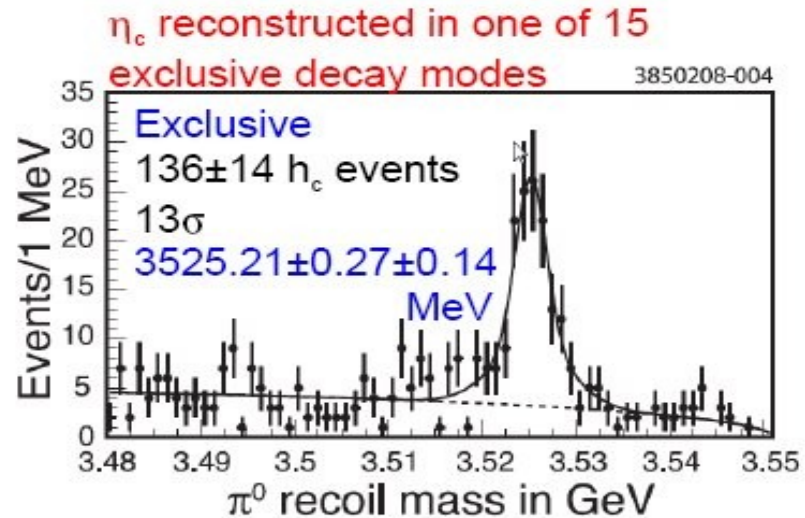

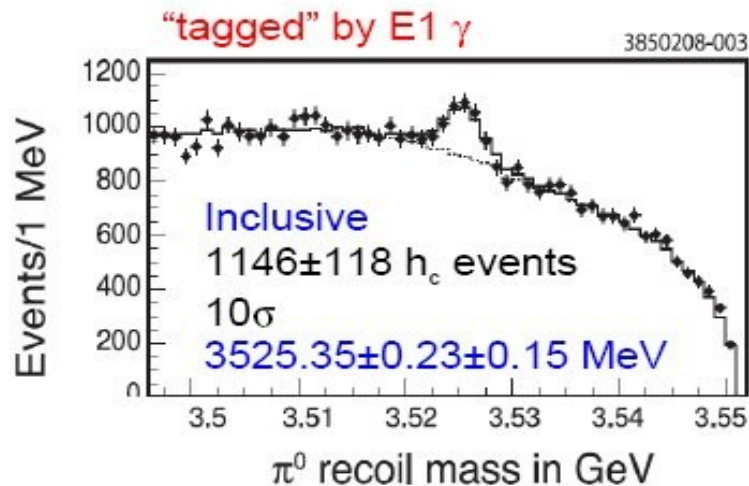

$$B(\eta_c \rightarrow \gamma\gamma) = (0.6^{+1.3}_{-0.5} \pm 0.1) \times 10^{-4} \quad (< 3 \times 10^{-4} \text{ at } 90\% \text{ CL}),$$

consistent with PDG.

h_c Mass: New, updated measurement

CLEO-c arXiv:0805.4599 [hep-ex]

- A factor of ~ 9 larger statistics than in the initial publication

Result: $M(h_c) = (3525.28 \pm 0.19 \pm 0.12)$ MeV

cf. $\langle M(\chi_{cJ}) \rangle = (3525.30 \pm 0.11)$ MeV (PDG)

\rightarrow HF splitting of 1P states is negligibly small!

Invariant mass of η decay products:

M(CLEO) – M(PDG06) (MeV)

16k fully reconstructed events

η Mass

CLEO: $M(\eta) = 547.785 \pm 0.017 \pm 0.057$ MeV
 PRL 99, 122002 (2007) (arXiv:0707.1810)

KLOE: $M(\eta) = 547.874 \pm 0.007 \pm 0.029$ MeV
 arXiv:0707.4616 (LP07 contribution)
 JHEP 712, 073 (2007)

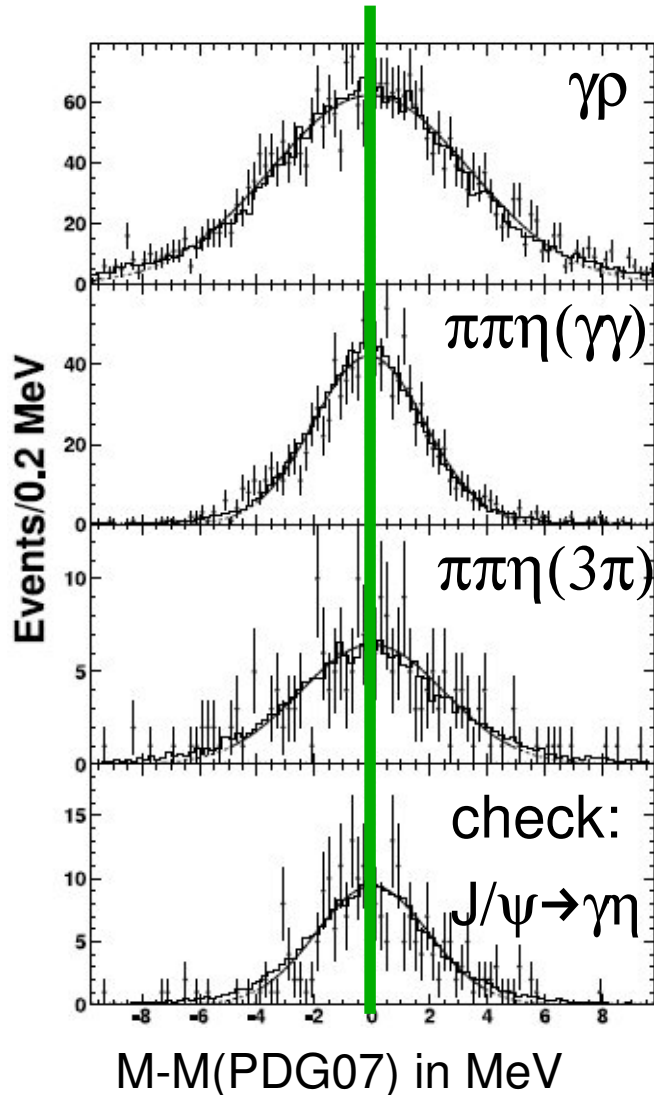

Malhke,

η' Mass

Use $\psi(2S) \rightarrow \pi^+\pi^- J/\psi$, $J/\psi \rightarrow \gamma \eta'$

Similar technique as in η mass measurement

Result:

(CLEO arXiv:0806.2344, subm' to PRL)

$$M(\eta') = (957.793 \pm 0.054 \pm 0.036) \text{ MeV}$$

consistent with and substantially more precise than previous world average

Implication for the pseudoscalar η - η' mixing angle:

$$\phi_P = (41.461 \pm 0.008)^\circ \quad (\text{Jones \& Scadron 1979})$$

Agrees with ϕ_P from BFs: flavor symm' breaking small?

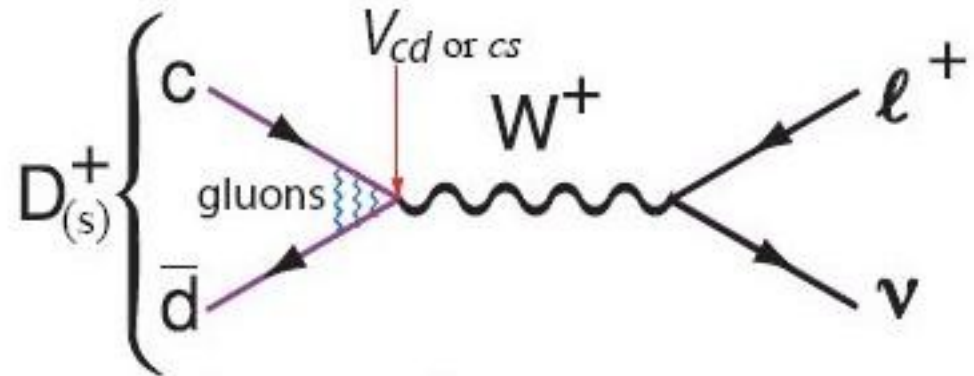

$$\tan^2 \phi_P = \frac{(M_{\eta'}^2 - 2M_K^2 + M_\pi^2)(M_\eta^2 - M_\pi^2)}{(2M_K^2 - M_\pi^2 - M_{\eta'}^2)(M_{\eta'}^2 - M_\pi^2)}$$

Charm: Decay Constants f_D and f_{D_s}

c and \bar{q} can annihilate, probability is proportional to wave function overlap

Feynman diagram

in Standard Model :

In general for all pseudoscalars:

$$\Gamma(P^+ \rightarrow \ell^+ \nu) = \frac{1}{8\pi} G_F^2 f_P^2 m_\ell^2 M_P \left(1 - \frac{m_\ell^2}{M_P^2}\right)^2 |V_{Qq}|^2$$

Calculate, or measure if V_{Qq} is known, here take $V_{cd} = V_{us} = 0.2256$

f_D & f_{D_s} : New LQCD Calculations

- Follana et al HPQCD & UKQCD collaborations (PRL 100, 062002 (2008))

New predictions of

$$f_{D^+} = 207 \pm 4 \text{ MeV}$$

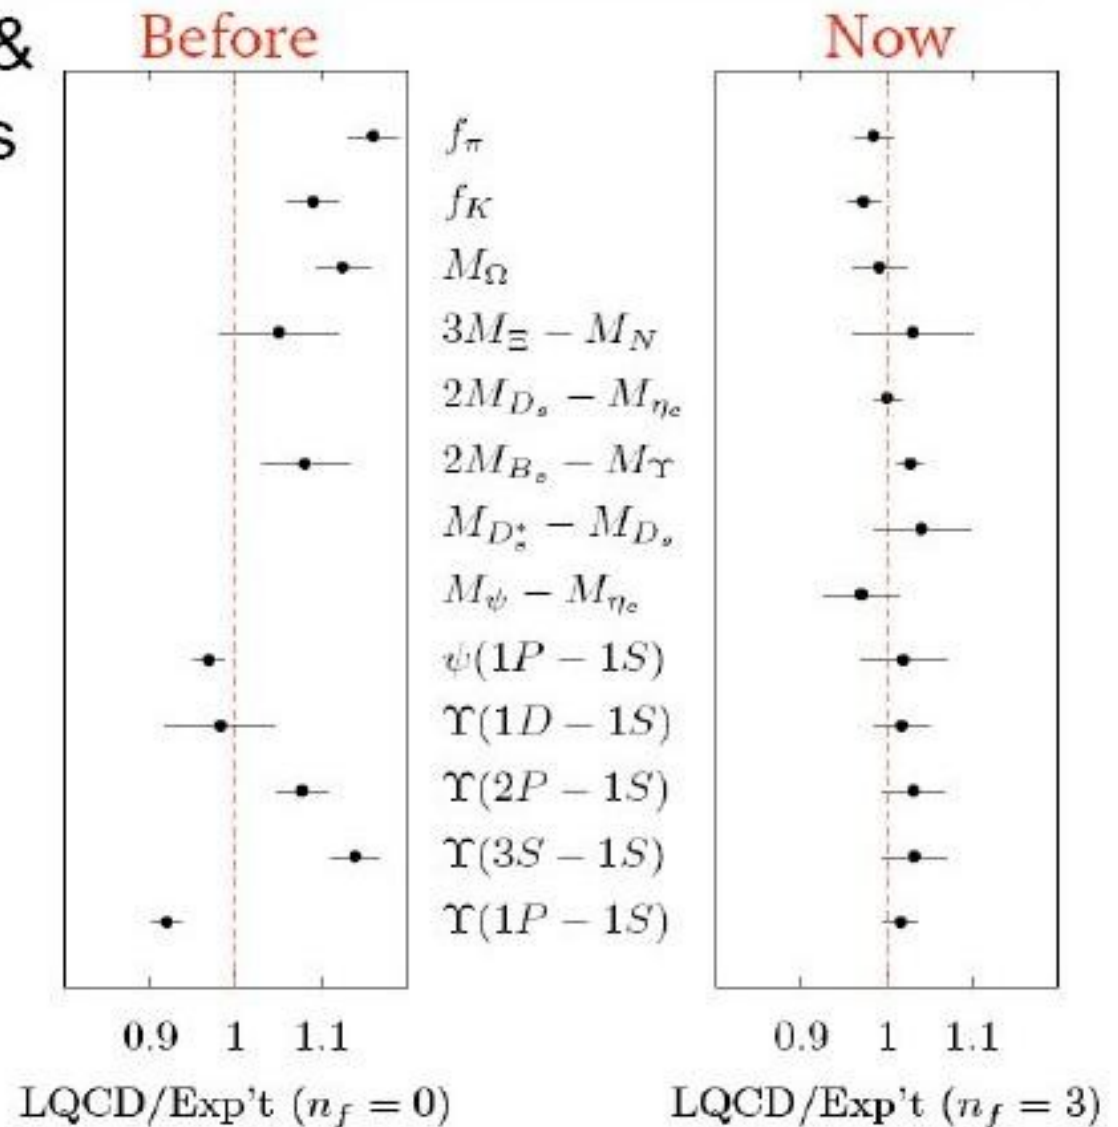

$$f_{D_s} = 241 \pm 3 \text{ MeV}$$

- Older unquenched from FNAL+MILC +HPQCD are:

$$f_{D^+} = 201 \pm 3 \pm 17 \text{ MeV}$$

$$f_{D_s} = 249 \pm 3 \pm 16 \text{ MeV}$$

(Aubin et al., PRL 95, 122002 (2005))

Basic Technique for $D^+ \rightarrow \mu^+ \nu$

CLEO-c, 818/pb

- Fully reconstruct a D^- , and count total # of tags
- Seek events with only one additional oppositely charged track within $|\cos\theta| < 0.9$ & no additional photons > 250 MeV (to veto $D^+ \rightarrow \pi^+\pi^0$)
- Charged track must deposit only minimum energy (from ionization) in calorimeter < 300 MeV
- Compute MM^2 . If close to zero then almost certainly we have a $\mu^+\nu$ decay.

$$MM^2 = (E_{D^+} - E_{\ell^+})^2 - (\vec{p}_{D^+} - \vec{p}_{\ell^+})^2$$

We know $E_{D^+} = E_{\text{beam}}$, $\mathbf{p}_{D^+} = -\mathbf{p}_{D^-}$

$D^+ \rightarrow \mu^+ \nu$ Signal & Fit

$\tau\nu/\mu\nu$ **fixed** to SM ratio:

-- $B(D^+ \rightarrow \mu^+ \nu) = (3.82 \pm 0.32 \pm 0.09) \times 10^{-4}$

-- $f_{D^+} = (205.8 \pm 8.5 \pm 2.5) \text{ MeV}$

$\tau\nu/\mu\nu$ ratio allowed to **float**:

-- $B(D^+ \rightarrow \mu^+ \nu) = (3.93 \pm 0.35 \pm 0.09) \times 10^{-4}$

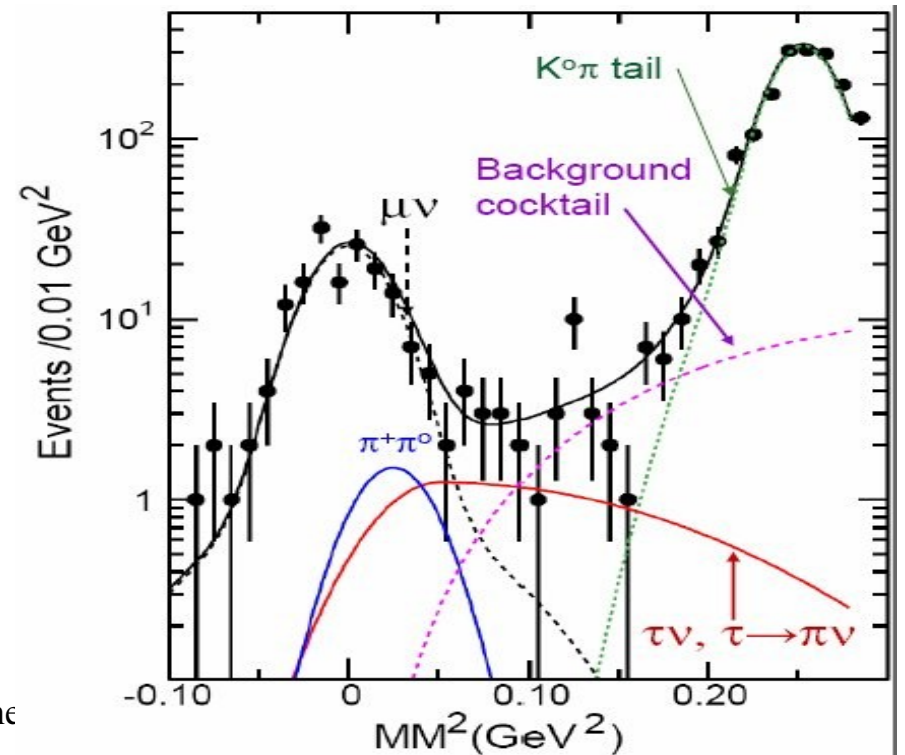

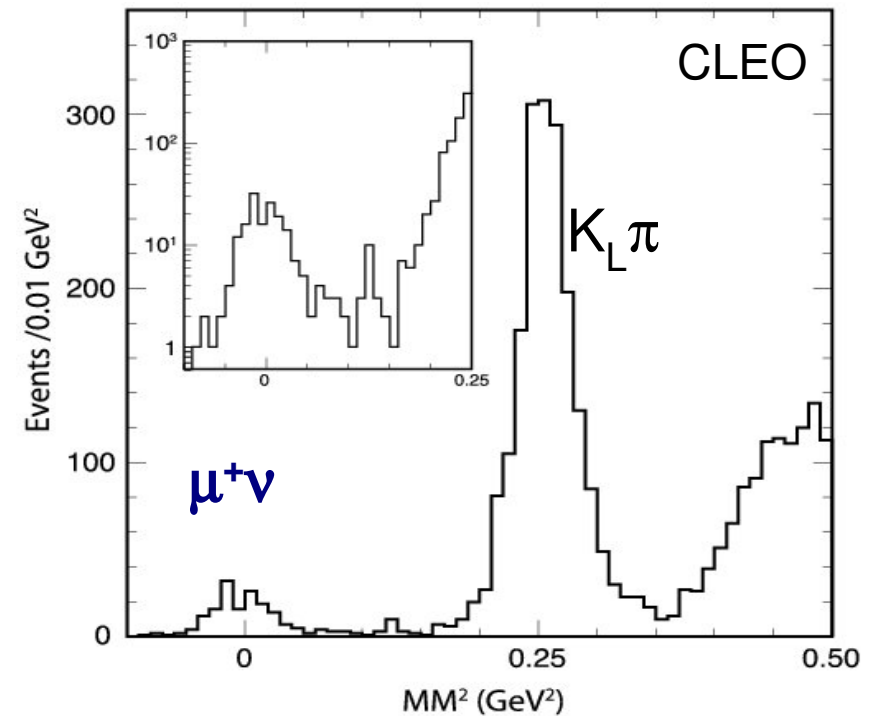

-- $f_{D^+} = (207.6 \pm 9.3 \pm 2.5) \text{ MeV}$

(arXiv:0806.2112, subm' to PRD)

Theory (Follana et al.):

-- $f_{D^+} = (208 \pm 4) \text{ MeV}$

Excellent agreement!

f_{D_s} : use $e^+e^- \rightarrow D_s D_s^*$ at 4170 MeV

- Reconstruct D_s^- , similar invariant mass distributions as for absolute \mathcal{B} analysis
- Find the γ from the D_s^* & compute MM^2 from D_s^- & γ

$$MM^{*2} = (E_{CM} - E_{D^-} - E_{\gamma})^2 - (\vec{p}_{D^-} - \vec{p}_{\gamma})^2$$

- Select combinations consistent with a missing D_s^+ & count the number
- Find MM^2 from candidate muons in the tag sample, where

$$MM^2 = (E_{CM} - E_{D^-} - E_{\gamma} - E_{\mu})^2 - (\vec{p}_{D^-} - \vec{p}_{\gamma} - \vec{p}_{\mu})^2$$

For further details, cf. S.Stone (CLEO), arXiv:0806.3921, and talk at FPCP08)

- Reconstruction of tagging D_s^- $e^+e^- \rightarrow D_s D_s^*$
2/3 of full CLEO-c sample

Counting tagged D_s^+ events in $e^+e^- \rightarrow D_s D_s^*$: $30,848 \pm 695$

MM^{*2}

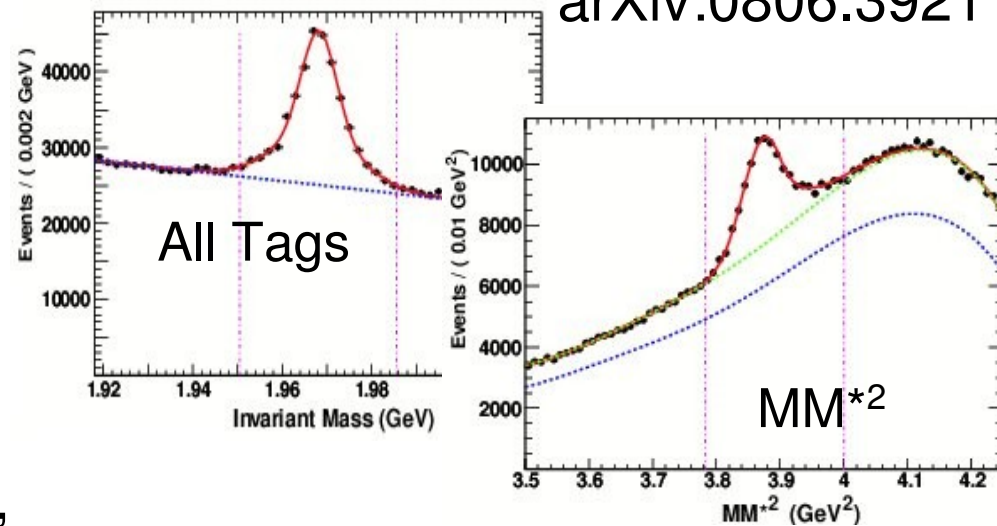

$D_s^+ \rightarrow \mu^+ \nu, \tau^+ \nu$ Signal & Fit (CLEO PRELIMINARY!)

arXiv:0806.3921

$\tau\nu/\mu\nu$ fixed to SM ratio. Average the result with that from $D_s \rightarrow \tau(e\nu\nu) \nu$

analysis (PRL 100, 161801 (2008):

-- $f_{D_s^+} = (267.9 \pm 8.2 \pm 3.9) \text{ MeV}$

Agrees with Belle: $(269.6 \pm 8.3) \text{ MeV}$,
 arXiv:0709.1340 but **disagrees with**
Follana et al.: $(241 \pm 3) \text{ MeV}$, by 3.2σ !

Are the calculations reliable?

If not then what about f_B, f_{B_s} , CKM fits?

If yes then are we seeing New Physics

(leptoquarks, charged Higgs, R-parity violating SUSY,...)? cf. Dobrescu & Kronfeld, arXiv:0803.0512,
 or Kundu & Nandi, arXiv:0803.1898

Discovery of $D_s^+ \rightarrow p\bar{n}$

- Use same technique as for $\mu^+\nu$, but plot MM from an identified proton
- No background
- First example of a charm meson decaying into baryons

arXiv:0803.1118v2 [hep-ex]

PRL 100, 181802 (2008)

$$B(D_s^+ \rightarrow p\bar{n}) = (1.30 \pm 0.36^{+0.12}_{-0.16}) \times 10^{-3}$$

- Consequences for understanding W annihilation dynamics
see Chen, Cheng & Hsiao arXiv:0803.2910v3 [hep-ph]

Summary

Charmonium is an excellent testing ground for QCD:

- Spectroscopy: η_c , h_c
- Can “dial” gluonic environments: $\psi(2S)$, J/ψ , χ_{cJ}
- Production of lighter systems ($\pi^+\pi^-$ tagging is wonderful!)

Decay constants: f_D in excellent agreement with LQCD,

f_{D_s} in 3.2σ disagreement with LQCD.

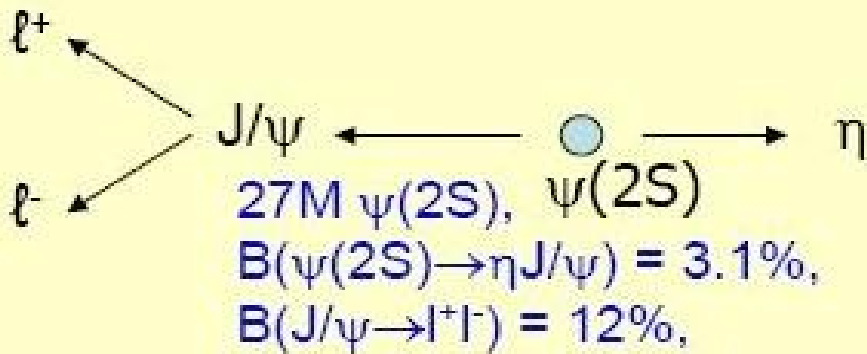

Who is to blame – exp't, theory, or NP ?

First Observations & Discovery: $J/\psi \rightarrow 3\gamma$, $D_s \rightarrow p n$

CLEO-c is laying good groundwork for BES III

Backup Slides

η branching fractions

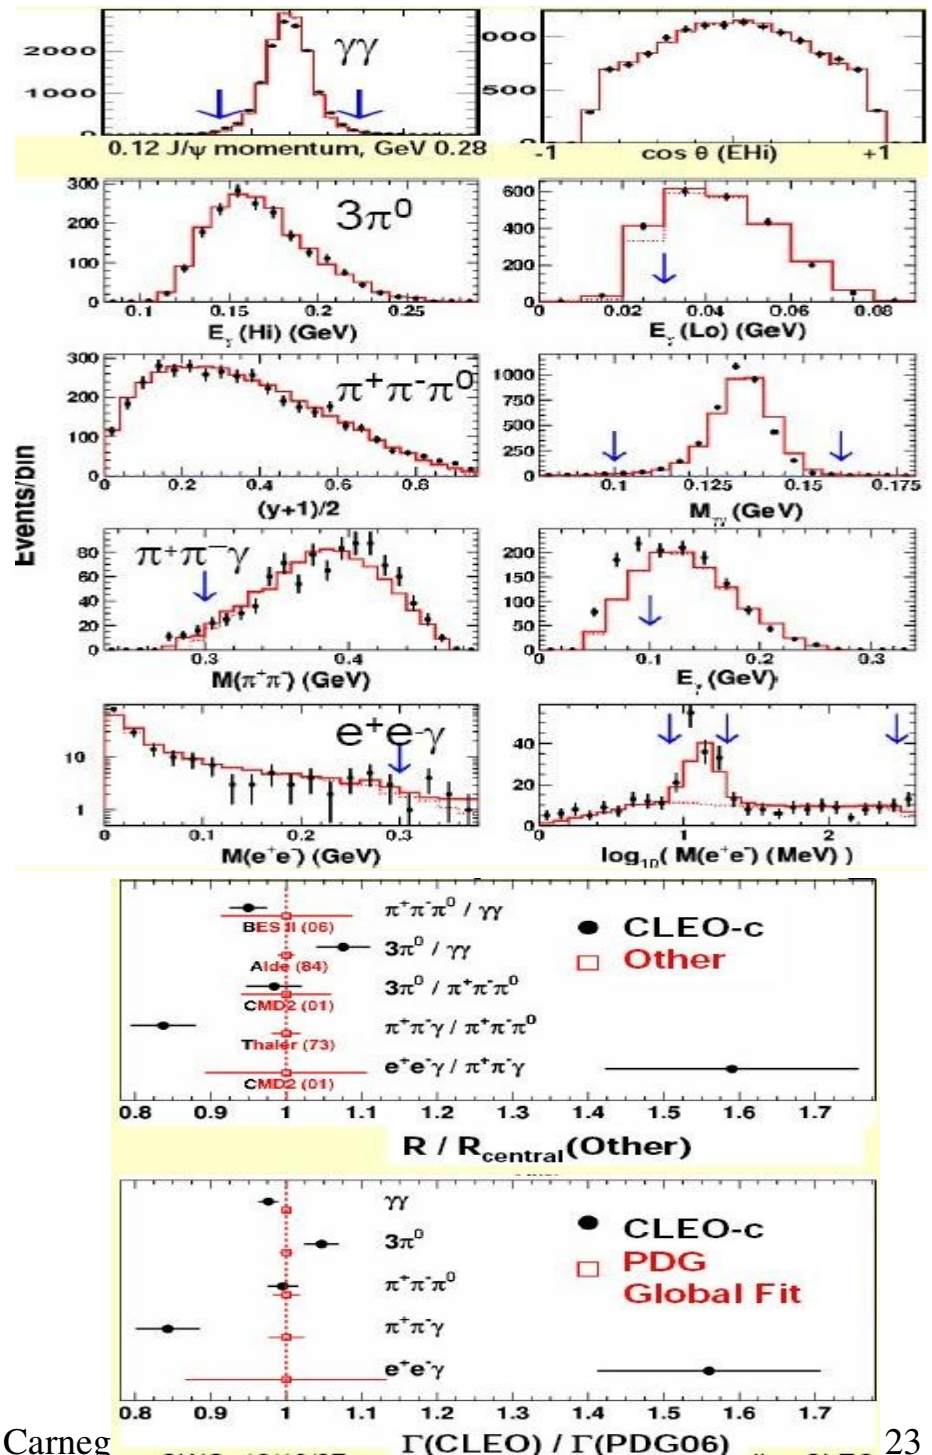

Fully reconstruct five final states:

$\gamma\gamma + 3\pi^0 + \pi^+\pi^-\pi^0 + \pi^+\pi^-\gamma + e^+e^-\gamma$
 38.5 34.0 22.6 4.0 0.9%

Follow PDG procedure: sum of the above five modes is $\sim 100\%$
 \Rightarrow build absolute Br's from ratios

$\pi^+\pi^-\gamma$ and $e^+e^-\gamma$: 3σ deviation

CLEO, PRL 99, 122001 (2007) or arXiv:0707.1601

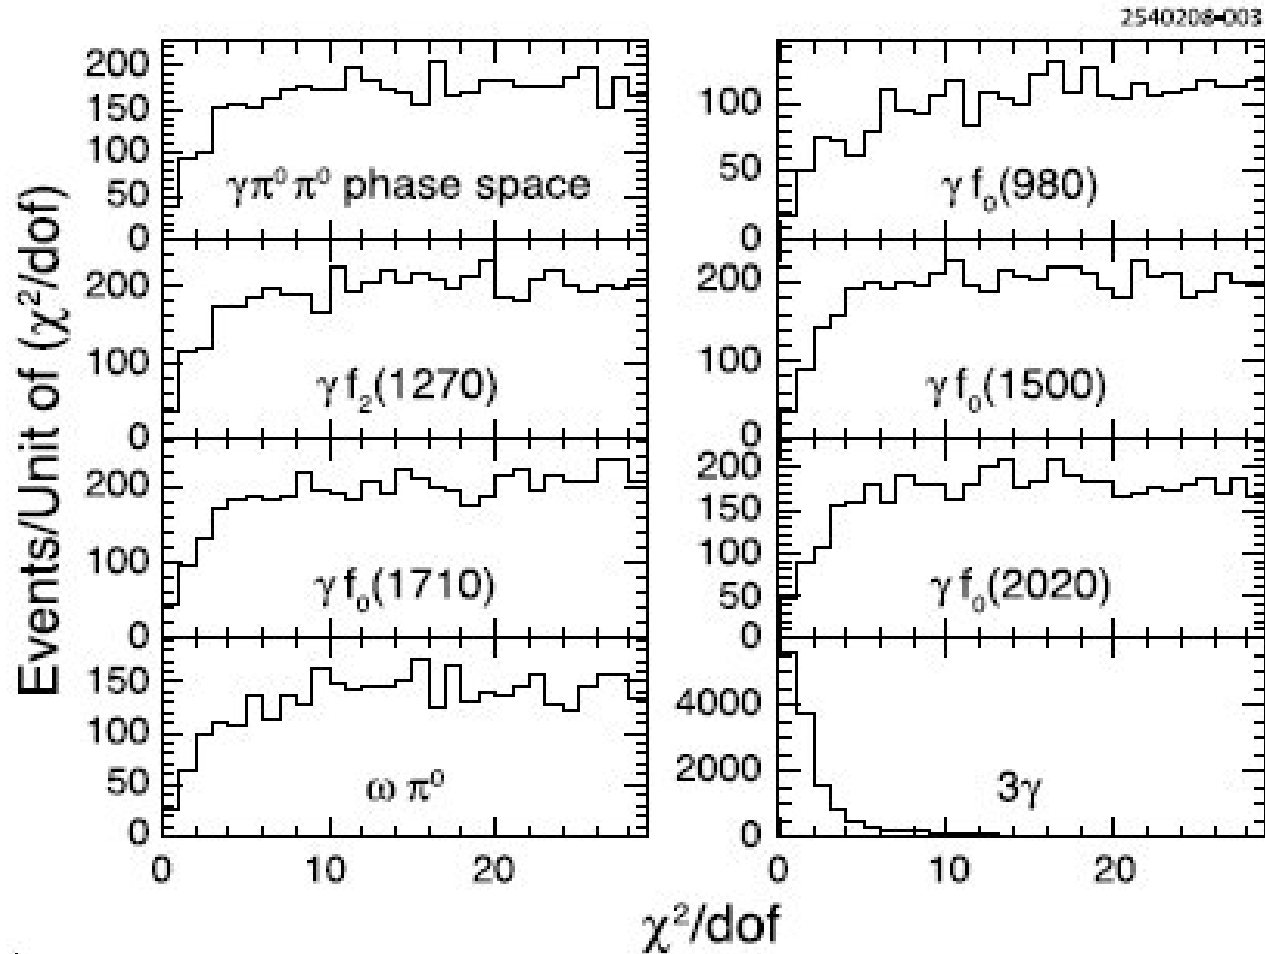

FIG. 3: The distribution of $\chi^2/\text{d.o.f.}$ for $J/\psi \rightarrow 3\gamma$ (lower right) and several sources of $\gamma\pi^0\pi^0$ background.

CLEO-c method

CLEO arXiv:0805.0252 [hep-ex]

- $B(J/\psi \rightarrow \gamma \eta_c)$ difficult to measure from inclusive photon spectrum since η_c is broad (25 MeV) and the photon is relatively soft (large background of unknown shape)

- CLEO-c method:

$$B(J/\psi \rightarrow \gamma \eta_c) =$$

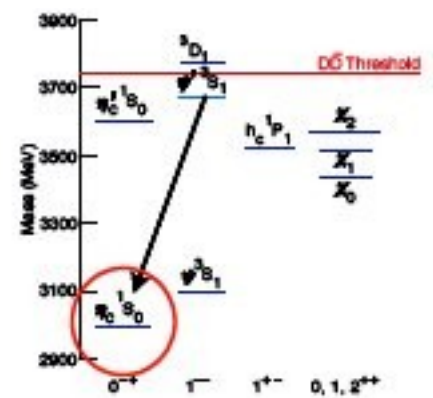

$$B(\psi' \rightarrow \gamma \eta_c) \times \frac{A/B}{B(\psi' \rightarrow \gamma \eta_c) \times B(\eta_c \rightarrow X)}$$

Measure from inclusive photon spectrum. The photon is hard, thus backgrounds are under control.

Use exclusive reconstruction of a large number of possible final states X (suppresses the backgrounds). Take the ratio to cancel unknown $B(\eta_c \rightarrow X)$

$\Psi' \rightarrow \gamma \eta_c$

- Tag η_c decay using 13 signal-rich decay modes (some new)
- Perform full event kinematic fit to sharpen photon resolution
- The η_c line shape in hindered M1 transitions is nontrivial and cannot be easily fit by a Breit-Wigner (even when energy-dependent phase space and matrix element terms are included)

$$\Gamma_{n^3S_1 \rightarrow n^1S_0 \gamma} = \frac{4}{3} \alpha e_Q^2 \frac{k_\gamma^3}{m^2} \left| \int_0^\infty dr r^2 R_{n'0}(r) R_{n0}(r) j_0\left(\frac{k_\gamma r}{2}\right) \right|^2$$

c.f.: Brambilla et al, PRD 73,054005 (2006)

$$j_0(k_\gamma r/2) = 1 - (k_\gamma r)^2/24 + \dots$$

$$\Gamma(\Psi' \rightarrow \gamma \eta_c) [n \neq n'] \propto E_\gamma^7$$

$$\Gamma(J/\psi \rightarrow \gamma \eta_c) [n = n'] \propto E_\gamma^3$$
